SCENARIO

A media analytics company has recently built a news monitoring platform that aggregates articles from multiple outlets into one central system. At the heart of this platform lies a text-driven **article classification and clustering engine** that must automatically organise incoming news articles into the correct topic category.

The company's leadership is eager: a well-performing article classification system will dramatically reduce editorial back-and-forth, improve the relevance of client-facing news digests, and streamline internal content workflows.

This is where you come in. You are hired as a data science consultant. Fresh from successfully completing **IM0503 Data Analytics**, you now have the skills and tools to clean this dataset, explore its structure, and build models that can both cluster articles by topic and classify them into the correct category.

DATASET DESCRIPTION

The company has compiled a dataset of historical BBC news articles, originally published between 2004 and 2005 across five editorial desks. The dataset has been extracted from the archive and covers a wide range of topics, from financial reporting and political analysis to sports coverage and technology news. Note that the dataset provided may contain data quality issues that must be identified and resolved before analysis.

ATTRIBUTE	DESCRIPTION
CATEGORY	The editorial category the article belongs to. Possible values: business, entertainment, politics, sport, tech.
FILENAME	The original filename of the article in the BBC archive (e.g. 001.txt).
TITLE	The headline of the news article as published.
CONTENT	The full body text of the news article.
